# 1 Performance Profile

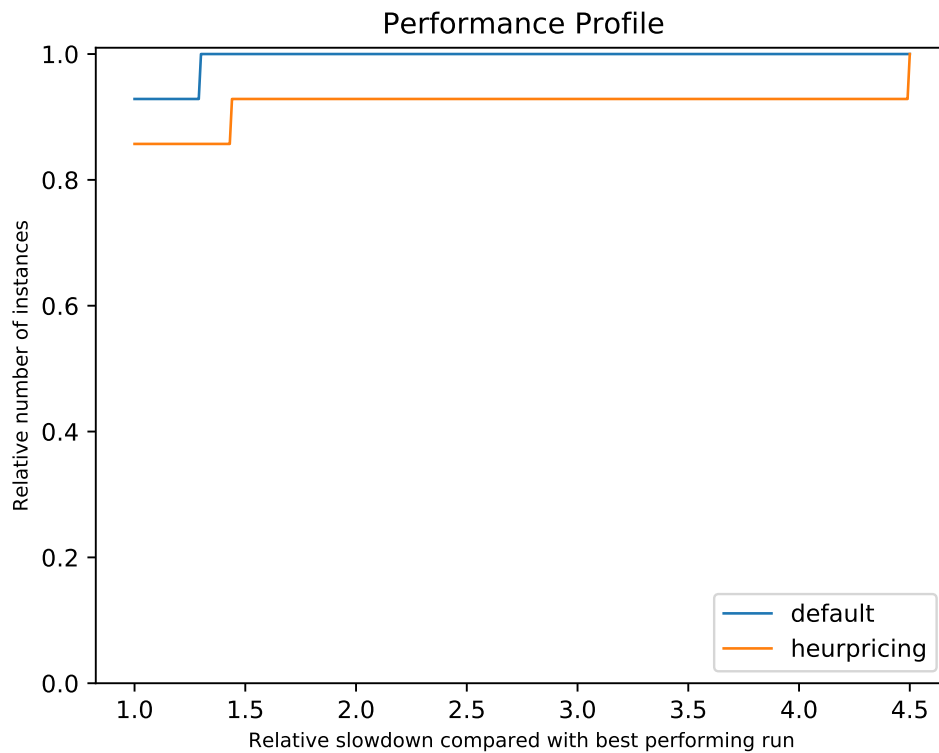

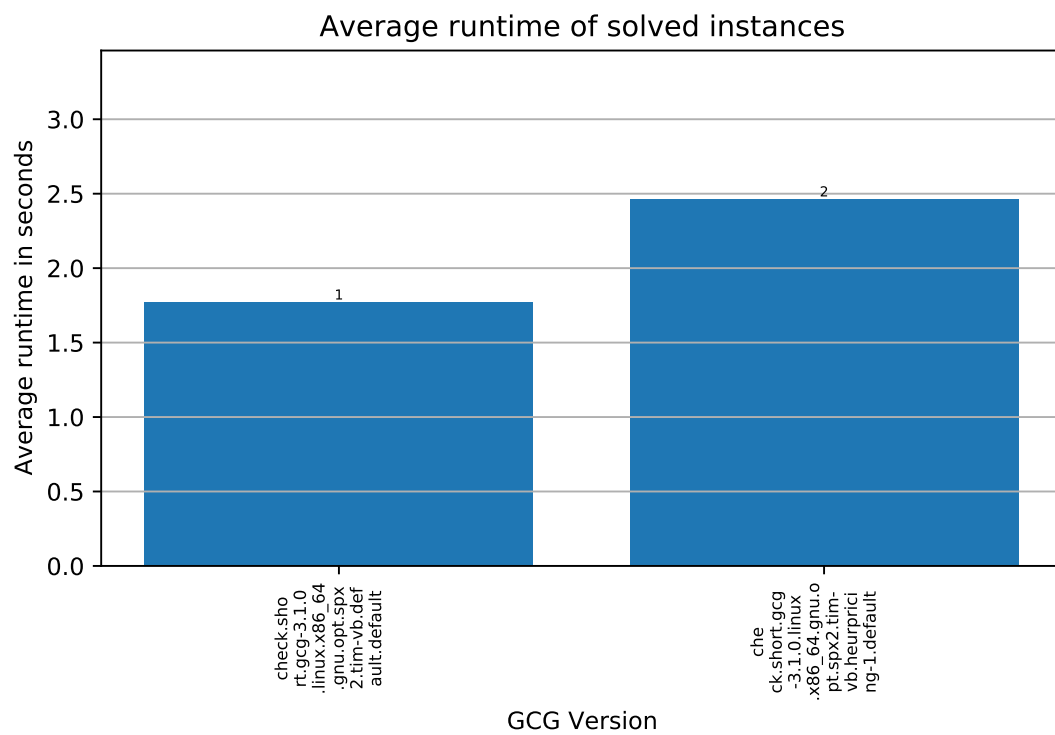

Figure 1: The best performing run is a line with steepness  $m = 0$  and  $y$ -intercept  $f(0) = 1$ . For all other runs, the integral over the shown  $x$ -interval is lower or equal to the one of the best performing run. The plot can be interpreted as follows: For each point  $(x, y)$ ,  $x$  represents the performance in multiples of the duration the best performing run needed and  $y$  represents the likelihood for the setting to perform as fast as the best performing run times the multiples. If the underlying function of one setting has first-order stochastic dominance over another, it can be considered to be faster for this test set.

## 2 General Visualizations

Testset: short

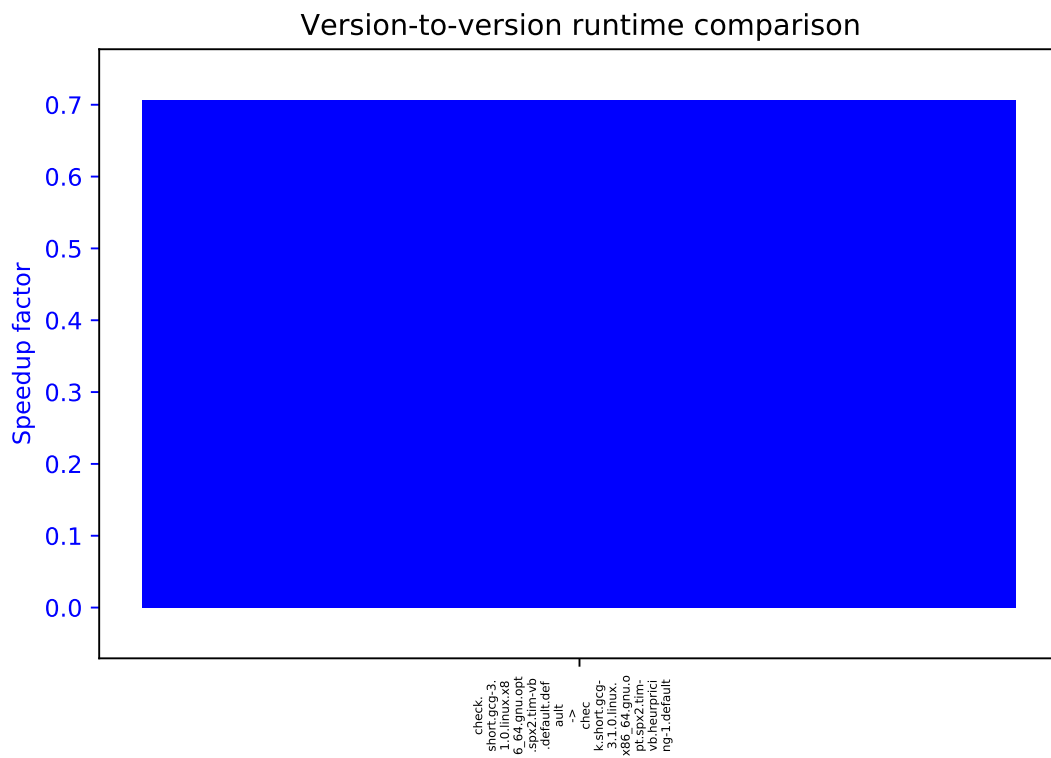

Figure 2: Average solving time.

Visualization Path: `plots/general/averagesolvetime.pdf`

Testset: short  
The total number of instances in the test (per version) was 14

Figure 3: Comparison of Fails.  
Visualization Path: `plots/general/failcomparison.pdf`

Testset: short  
 The total number of instances in the test (per version) was 14.

Figure 4: Version to version runtime comparison.  
 Visualization Path: `plots/general/runtimecomparison.pdf`

Testset: short

Figure 5: Runtimes per test run.  
 Visualization Path: `plots/general/runtimes.pdf`

Testset: short

Figure 6: Time comparison per status.  
Visualization Path: `plots/general/timecomparisonperstatus.pdf`

### 3 Time Distribution Plot

Figure 7: Time Comparison Bar Chart.  
Visualization Path: `plots/timedist/short.timedist.compare.pdf`

The total runtime of testset short.out (#2 from outside, 14 instances) was 31.73s.  
 The total runtime of testset short.out (#1 from outside, 1 instances) was 22.56s.

Figure 8: Time Comparison Pie Chart.

## 5 Bounds Development (Root Node)

### 5.1 Instance: gap4\_2

Figure 15: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/gap4_2.txt.compare.bounds_time.pdf`

## 5.2 Instance: gap8\_4

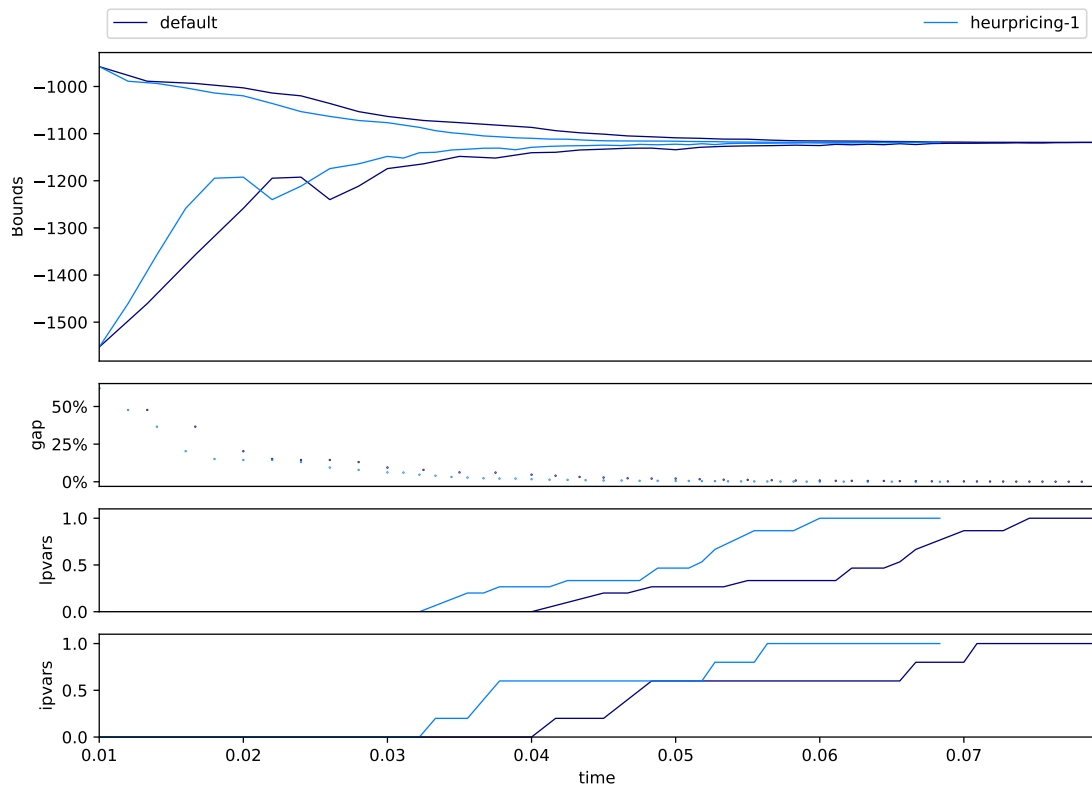

Figure 16: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/gap8_4.txt.compare.bounds_time.pdf`

### 5.3 Instance: N1C1W4\_M

Figure 17: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table “root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/N1C1W4_M.BPP.compare.bounds.time.pdf`

## 5.4 Instance: N1C2W2\_O

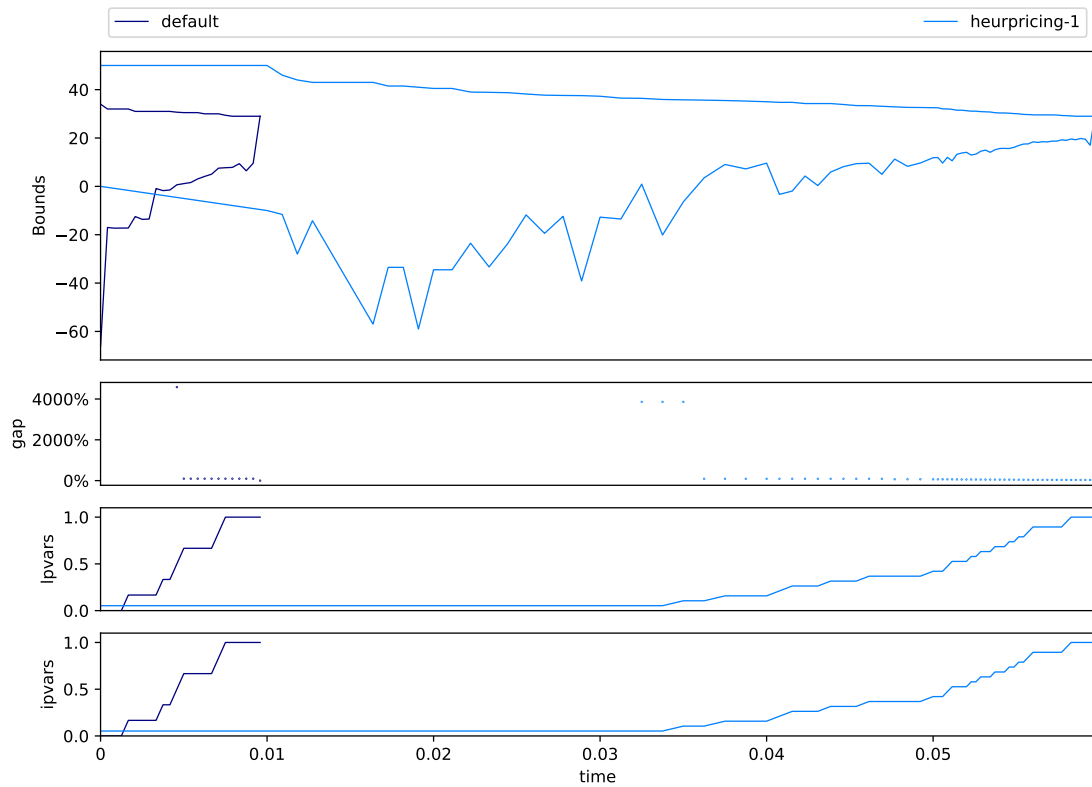

Figure 18: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table “root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/N1C2W2_0.BPP.compare.bounds.time.pdf`

## 5.5 Instance: N1C3W1\_A

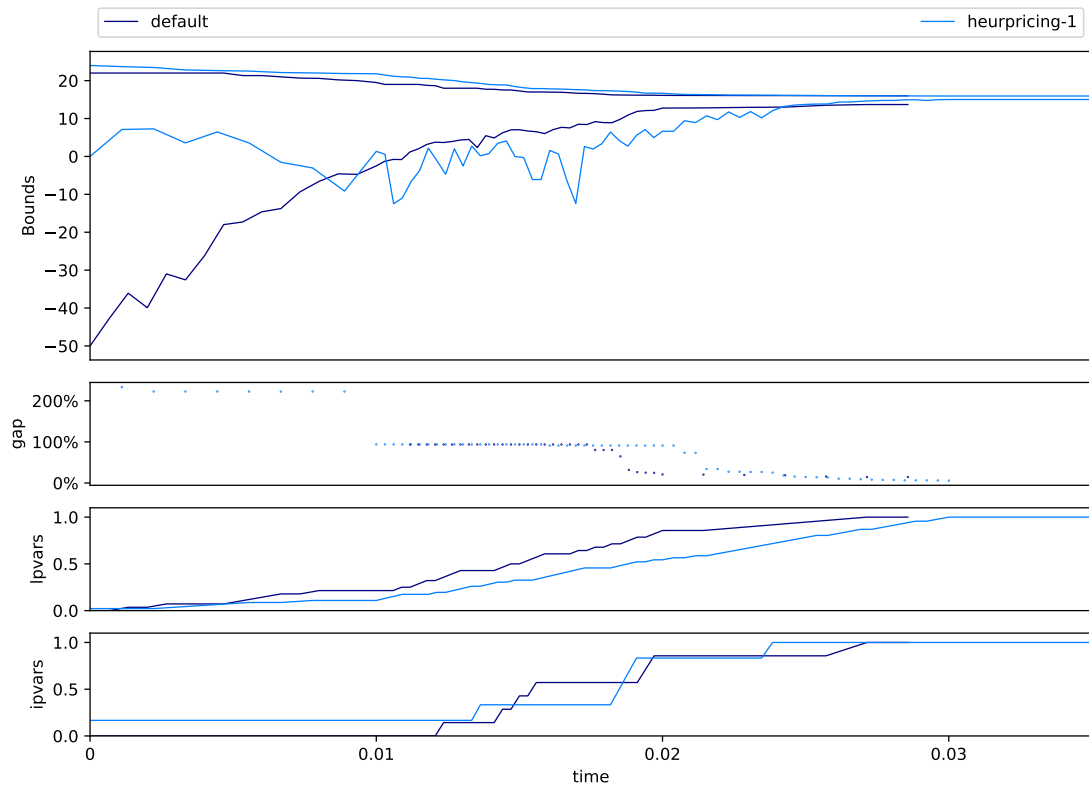

Figure 19: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table “root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/N1C3W1_A.compare.bounds_time.pdf`

## 5.6 Instance: noswot

Figure 20: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table “root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/noswot.compare.bounds_time.pdf`

## 5.7 Instance: p1250-2

Figure 21: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table “root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/p1250-2.compare.bounds_time.pdf`

## 5.8 Instance: p1650-2

Figure 22: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/p1650-2.txt.compare.bounds_time.pdf`

## 5.9 Instance: p2050-1

Figure 23: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/p2050-1.txt.compare.bounds_time.pdf`

## 5.10 Instance: TEST0055

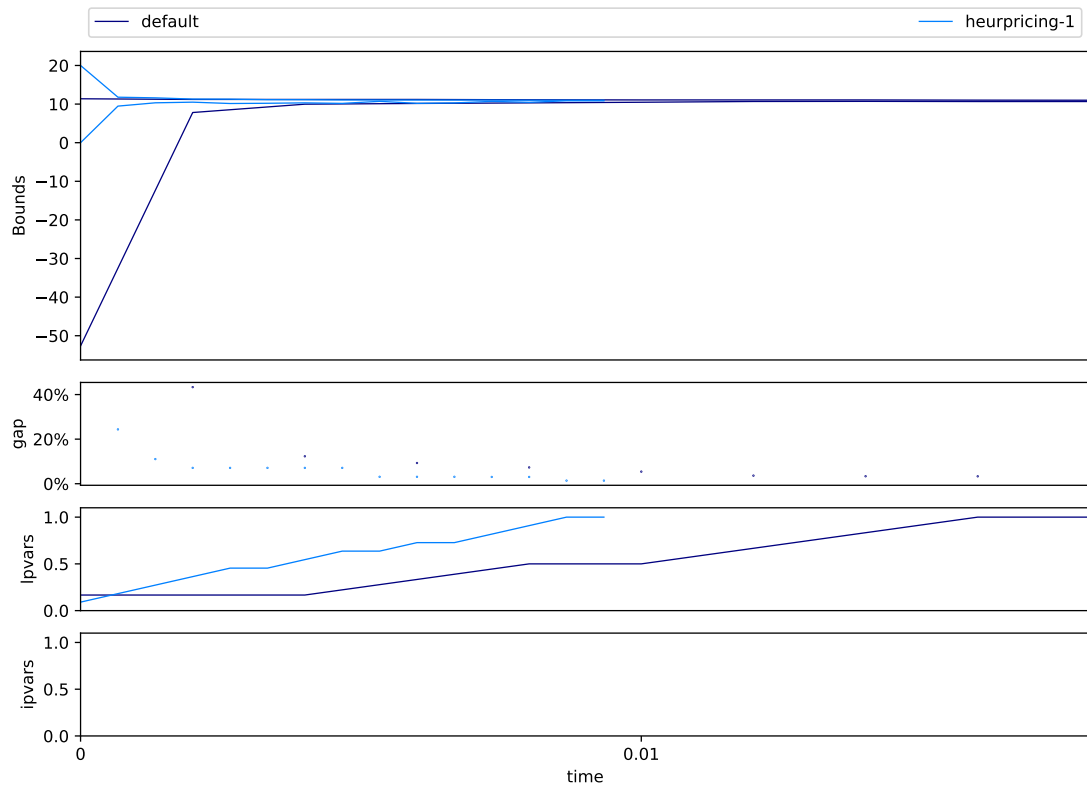

Figure 24: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table “root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/TEST0055.compare.bounds_time.pdf`

## 5.11 Instance: TEST0059

Figure 25: The top subplot shows the development of the primal and dual bounds in the RMP during the pricing in the root node as given by the table “root bounds” printed by GCG. Every change represents a pricing iteration and the resulting changes to the bounds. The bounds are complemented by a gap plot. The other two subplots illustrate the point in time in the pricing at which the columns that are finally in the basis are generated.

Visualization Path: `plots/bounds/TEST0059.compare.bounds_time.pdf`
